(57) **ABSTRACT**

A light source, for example a light emitting diode, can emit
light and have an associated optical axis. The source can be
deployed in applications where it is desirable to have illumi-
nation biased laterally relative to the optical axis, such as in a
street luminaire where directing light towards a street is ben-
eficial. The source can be coupled to an optic that comprises
an inner surface facing the source and an outer surface that is
opposite the inner surface. The inner surface can comprise a
refractive surface that receives light headed away from the
optical axis of the light source, for example opposite the
street. The refractive surface can form the received light into
a beam. The outer surface of the optic can reflect the beam
back across the optical axis, for example so that light headed
away from the street is redirected towards the street.

METHOD AND SYSTEM FOR MANAGING LIGHT FROM A LIGHT EMITTING DIODE

CROSS REFERENCE TO RELATED APPLICATIONS

This application claims priority to U.S. Provisional Patent Application No. 61/447,173 filed Feb. 28, 2011 in the name of Kevin Charles Broughton and entitled "Method and System for Managing Light From a Light Emitting Diode," the entire contents of which are hereby incorporated herein by reference.

FIELD OF THE TECHNOLOGY

The present technology relates to managing light emitted by one or more light emitting diodes ("LEDs"), and more specifically to an optical element that can form a beam from a section of such emitted light and that can apply total internal reflection to direct such a beam towards a desired location.

BACKGROUND

Light emitting diodes are useful for indoor and outdoor illumination, as well as other applications. Many such applications would benefit from an improved technology for managing light produced by a light emitting diode, such as forming an illumination pattern matched or tailored to application parameters.

For example, consider lighting a street running along a row of houses, with a sidewalk between the houses and the street. Conventional, unbiased light emitting diodes could be mounted over the sidewalk, facing down, so that the optical axis of an individual light emitting diode points towards the ground. In this configuration, the unbiased light emitting diode would cast substantially equal amounts of light towards the street and towards the houses. The light emitted from each side of the optical axis continues, whether headed towards the street or the houses. However, most such street lighting applications would benefit from biasing the amount of light illuminating the street relative to the amount of light illuminating the houses. Many street luminaires would thus benefit from a capability to transform house-side light into street-side light.

In view of the foregoing discussion of representative shortcomings in the art, need for improved light management is apparent. Need exists for a compact apparatus to manage light emitted by a light emitting diode. Need further exists for an economical apparatus to manage light emitted by a light emitting diode. Need further exists for a technology that can efficiently manage light emitted by a light emitting diode, resulting in energy conservation. Need further exists for an optical device that can transform light emanating from a light emitting diode into a desired pattern, for example aggressively redirecting one or more selected sections of the emanating light. Need further exists for technology that can directionally bias light emitted by a light emitting diode. Need exists for improved lighting, including street luminaires, outdoor lighting, and general illumination. A capability addressing such need, or some other related deficiency in the art, would support cost effective deployment of light emitting diodes in lighting and other applications.

SUMMARY

An apparatus can process light emitted by one or more light emitting diodes to form a desired illumination pattern, for example successively applying refraction and total internal

2

reflection to light headed in certain directions, resulting in beneficial redirection of that light.

In one aspect of the present technology, a light emitting diode can produce light and have an associated optical axis. A body of optical material can be oriented with respect to the light emitting diode to process the produced light. The body can be either seamless or formed from multiple elements joined or bonded together, for example. A first section of the produced light can transmit through the body of optical material, for example towards an area to be illuminated. The body of optical material can redirect a second section of the produced light, for example so that light headed in a non-strategic direction is redirected towards the area to be illuminated. A refractive surface on an interior side of the body of optical material can form a beam from the second section of the produced light. The beam can propagate in the optical material at an angle relative to the optical axis of the light emitting diode while heading towards a reflective surface on an exterior side of the body of optical material. Upon beam incidence, the reflective surface can redirect the beam out of the body of optical material, for example through a surface region that refracts the beam as the beam exits the body of optical material. The refraction can cause beam divergence, for example. The reflective surface can be reflective as a result of comprising an interface between a transparent optical material having a relatively high refractive index and an optical medium having relatively low refractive index, such as a totally internally reflective interface between optical plastic and air. Alternatively, the reflective surface can comprise a coating that is reflective, such as a sputtered aluminum coating applied to a region of the body of optical material.

The foregoing discussion of managing light is for illustrative purposes only. Various aspects of the present technology may be more clearly understood and appreciated from a review of the following detailed description of the disclosed embodiments and by reference to the drawings and the claims that follow. Moreover, other aspects, systems, methods, features, advantages, and objects of the present technology will become apparent to one with skill in the art upon examination of the following drawings and detailed description. It is intended that all such aspects, systems, methods, features, advantages, and objects are to be included within this description, are to be within the scope of the present technology, and are to be protected by the accompanying claims.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is an illustration of an illumination system comprising a light emitting diode and an optic that manages light emitted by the light emitting diode according to certain exemplary embodiments of the present technology.

FIG. 2 is another illustration of the illumination system that FIG. 1 illustrates, further illustrating the optic managing representative rays emitted by the light emitting diode according to certain exemplary embodiments of the present technology.

FIG. 3 is a perspective view of the illumination system that FIG. 1 illustrates, wherein the optic is depicted as opaque to promote reader visualization according to certain exemplary embodiments of the present technology.

FIG. 4 is an plan view illustration of the illumination system that FIG. 1 illustrates, from a vantage point on the optical axis of the light emitting diode (looking at the light-emitting side of the optic) according to certain exemplary embodiments of the present technology.

FIGS. 5A, 5B, 5C, 5D, and 5E (collectively FIG. 5) are perspective views of the optic that FIG. 1 illustrates, where the optic is depicted as opaque to promote reader visualization.

3

tion according to certain exemplary embodiments of the present technology. FIGS. 5A, 5B, and 5C are taken from different vantage points looking at the light-emitting side of the optic. FIGS. 5D and 5E are taken from different vantage points looking at the light-receiving side of the optic.

FIGS. 6A, 6B, 6C, 6D, and 6E (collectively FIG. 6) are illustrations, from different perspectives, of a cavity on the light-receiving side of the optic that FIG. 1 illustrates, where the cavity is depicted as a solid, opaque three-dimensional rendering of the cavity to promote reader visualization according to certain exemplary embodiments of the present technology. Thus, FIG. 6 describes representative contours of the light-receiving side of the optic by depicting a computer generated solid of the type that could be formed by filling the cavity of the optic with a resin, curing the resin, and then separating the cured, solid resin from the optic.

FIG. 7 is an illustration of an array of optics for coupling to a corresponding array of light emitting diodes to provide an array of the illumination systems illustrated in FIG. 1 according to certain exemplary embodiments of the present technology.

FIG. 8 is a perspective view illustration of another optic for managing light emitted by a light emitting diode according to certain exemplary embodiments of the present technology.

FIG. 9 is an illustration in side view the optic that FIG. 8 illustrates and further illustrates the optic managing rays as could be emitted by an associated light emitting diode according to certain exemplary embodiments of the present technology.

FIG. 10 is an illustration of a representative computer-generated isofotocandle diagram of photometric performance for the optic of FIGS. 8 and 9 as coupled to a light emitting diode, with the lines depicting points of equal illuminance according to certain exemplary embodiments of the present technology.

FIG. 11 is an illustration in side view of another optic for managing light emitted by a light emitting diode and further illustrates the optic managing rays as could be emitted by an associated light emitting diode according to certain exemplary embodiments of the present technology.

FIG. 12 is an illustration in side view of a representative optical function of inner refractive features of the optic that FIG. 11 illustrates, wherein optical function of exterior features of the optic are ignored in order to promote reader visualization, according to certain exemplary embodiments of the present technology.

FIGS. 13A and 13B (collectively FIG. 13) are illustrations of an illumination system that comprises a light emitting diode coupled to another optic according to certain exemplary embodiments of the present technology.

FIG. 14 is an illustration of a representative computer-generated intensity polar plot for the illumination system that FIG. 13 illustrates according to certain exemplary embodiments of the present technology.

FIG. 15 is an illustration of a representative computer-generated illuminance plot for the illumination system that FIG. 13 illustrates according to certain exemplary embodiments of the present technology.

FIG. 16 is a plan view illustration of representative computer-generated ray traces for an embodiment of the illumination system that FIG. 13 illustrates according to certain exemplary embodiments of the present technology.

FIG. 17 is a plan view illustration of representative computer-generated ray traces for another embodiment of the illumination system that FIG. 13 illustrates according to certain exemplary embodiments of the present technology.

4

FIG. 18 is a flow chart of a process for managing light emitted by a light emitting diode according to certain exemplary embodiments of the present technology.

Many aspects of the technology can be better understood with reference to the above drawings. The elements and features shown in the drawings are not to scale, emphasis instead being placed upon clearly illustrating the principles of exemplary embodiments of the present technology. Moreover, certain dimensions may be exaggerated to help visually convey such principles. In the drawings, reference numerals designate like or corresponding, but not necessarily identical, elements throughout the several views.

DESCRIPTION OF EXEMPLARY EMBODIMENTS

A light source can emit light. In certain embodiments, the light source can be or comprise one or more light emitting diodes, for example. The light source and/or the emitted light can have an associated optical axis. The light source can be deployed in applications where it is desirable to bias illumination laterally relative to the optical axis. For example, in a street luminaire where the optical axis is pointed down towards the ground, it may be beneficial to direct light towards the street side of the optical axis, rather than towards a row of houses that are beside the street. The light source can be coupled to an optic that receives light propagating on one side of the optical axis and redirects that light across the optical axis. For example, the optic can receive light that is headed towards the houses and redirect that light towards the street.

The optic can comprise an inner surface facing the light source and an outer surface facing away from the light source, opposite the inner surface. The inner surface can comprise a refractive feature that receives light headed away from the optical axis of the light source, for example away from the street to be lighted. The refractive feature can comprise a convex lens surface bulging towards the light source, for example. The refractive feature can form the received, incident light into a beam headed along another optical axis. That optical axis can form an acute angle with respect to the optical axis of the light source itself. The outer surface of the optic can comprise a reflective feature that receives the beam. The reflective feature can comprise a totally internally reflective surface that reflects part, most, or substantially all of the beam back across the optical axis. In certain embodiments, the reflected beam exits the optic through a surface that causes the beam to diverge. The surface can be concave, for example. Accordingly, the optic can form a beam from light headed in a non-strategic direction and redirect the beam in a strategic direction.

Technology for managing light emitted by a light emitting diode or other light source will now be described more fully with reference to FIGS. 1-18, which describe representative embodiments of the present technology. FIGS. 1, 2, 3, 4, 5, and 6 describe certain representative embodiments of an illumination system comprising a light emitting diode and an associated optic. FIG. 7 describes certain representative embodiments of a sheet comprising a two-dimensional array of optics for managing light emitted by a corresponding array of light emitting diodes. FIGS. 8, 9, 10, 11, and 12 describe certain representative embodiments of an optic for managing light emitted by a light emitting diode. FIGS. 13, 14, 15, 16, and 17 describe certain representative embodiments of an optic for managing light emitted by a light emitting diodes. FIG. 18 describes a method or process for managing light

5

emitted by a light emitting diode. The various illustrated embodiments may be distinct and/or may have common features.

The present technology can be embodied in many different forms and should not be construed as limited to the embodiments set forth herein; rather, these embodiments are provided so that this disclosure will be thorough and complete, and will fully convey the scope of the technology to those having ordinary skill in the art. Furthermore, all “examples” or “exemplary embodiments” given herein are intended to be non-limiting and among others supported by representations of the present technology.

Turning now to FIGS. 1, 2, 3, 4, 5A, 5B, 5C, 5D, 5E, 6A, 6B, 6C, 6D, and 6E, these figures provide illustrations describing an exemplary embodiment of the present technology as may be applied for street illumination, as well as for other uses. As illustrated, an illumination system 5 can comprise a light emitting diode 10 that produces and emits light and an associated optic 100 managing the light so emitted. As discussed in further detail below, the light emitting diode 10 can produce light that is headed house side, opposite from the street (see light 210 illustrated in FIG. 2), and other light that is headed street side (opposite light 210 illustrated in FIG. 2). The optic 100 can redirect a substantial portion of the house-side light towards the street, where higher illumination intensity is often desired.

Those of ordinary skill having benefit of this disclosure will appreciate that street illumination is but one of many applications that the present technology supports. The present technology can be applied in numerous lighting systems and illumination applications, including indoor and outdoor lighting, automobiles, general transportation lighting, and portable lights, to mention a few representative examples without limitation.

FIGS. 1, 2, 3, 4, 5A, 5B, 5C, 5D, and 5E illustrate the optic 100 that manages light emitted by the light emitting diode 10. FIGS. 1 and 2 illustrate a side view, with FIG. 2 illustrating ray paths for a section 210 of light emitted from the light emitting diode 10. FIG. 3 illustrates a perspective view. FIG. 4 illustrates a plan view, specifically from a perspective looking down the optical axis 25 towards the light emitting dome 20 of the light emitting diode 10. Thus, if the light emitting diode 10 was mounted overhead so as to emit light towards the ground, the observer would be below the light emitting diode 10 looking straight up; and, if the light emitting diode was mounted on the ground so as to emit light towards the sky or a ceiling, the observer would be above the light emitting diode 10 looking straight down.

FIGS. 5A, 5B, 5C, 5D, and 5E illustrate the optic 100 as a three-dimensional rendering from five respective perspectives. The rendering of these illustrations represents the optic 100 as an opaque solid to facilitate visualization of transparent optical material. The views of FIGS. 5A, 5B, and 5C are taken from vantage points on the side of the optic 100 that is opposite the light emitting diode 10. Thus, the observer is on the side of the optic 100 that emits light (facing the outer side of the optic 100), but off the axis 25 shown in FIGS. 1, 3 and 4. The views of FIGS. 5D and 5E are taken from the LED-side of the optic 100, looking into a cavity 30 that the optic 100 comprises. Thus, the observer is on the side of the optic that receives light from the light emitting diode 10 (facing the inner side of the optic 100), again off the axis 25. The cavity 30 faces and receives light from the light emitting diode 10.

FIGS. 6A, 6B, 6C, 6D, and 6E illustrate the cavity 30 in the form of a three-dimensional solid rendering (from five perspective views) to facilitate reader visualization. In other words, to show exemplary surface contours of the exemplary

6

cavity 30, FIGS. 6A, 6B, 6C, 6D, and 6E depict a solid that would be formed by filling the cavity 30 with an opaque resin, curing the resin, and then removing the resulting solid.

The illustrated light emitting diode 10 (see FIGS. 1, 2 and 4) comprises an integral dome 20 that provides environmental protection to the light emitting diode's semiconductor materials and that emits the light that the light emitting diode 10 generates. The dome 20 projects or protrudes into the cavity 30 that the optic 100 forms. In certain exemplary embodiments, the dome 20 comprises material that encapsulates the light generating optical element of the light emitting diode 10, for example an optoelectronic semiconductor structure or feature on a substrate of the light emitting diode 10. In certain exemplary embodiments, the dome 20 radiates light at highly diverse angles, for example providing a light distribution pattern that can be characterized, modeled, or approximated as Lambertian.

The illustrated light emitting diode 10 comprises an optical axis 25 associated with the pattern of light emitting from the dome 20 and/or associated with physical structure or mechanical features of the light emitting diode 10. The term “optical axis,” as used herein, generally refers to a reference line along which there is some degree of rotational or other symmetry in an optical system, or a reference line defining a path along which light propagates through a system. Such reference lines are often imaginary or intangible lines. In the illustrated embodiment, the optical axis 25 lies in a reference plane 35 that sections the light emitting dome 20, and/or the associated light emission pattern of the light emitting diode 10, into two portions. Although illustrated in a particular position, the reference plane 35 can be positioned in other locations that may or may not be arbitrary. As will be appreciated by those of ordinary skill having benefit of this disclosure, a “reference plane” can be thought of as an imaginary or intangible plane providing a useful aid in describing, characterizing, or visualizing something.

The cavity 30 comprises an inner refractive surface 80 opposite an outer refractive surface 70. Light emitted from the street side of the dome 20 and that is headed street side is incident upon the inner refractive surface 80, transmits through the optic 100, and passes through the outer refractive surface 70. Such light may be characterized as a solid angle or represented as a ray or a bundle of rays. Accordingly, the light that is emitted from the light emitting diode 10 and headed street side continues heading street side after interacting with the optic 100. The inner refractive surface 80 and the outer refractive surface 70 cooperatively manipulate this light with sequential refraction to produce a selected pattern, for example concentrating the light downward or outward depending upon desired level of beam spread. In the illustrated embodiment, the light sequentially encounters and is processed by two refractive interfaces of the optic 100, first as the light enters the optic 100, and second as the light exits the optic 100.

One of ordinary skill in the art having benefit of the enabling teaching in this disclosure will appreciate that the inner refractive surface 80 and the outer refractive surface 70 can be formed to spread, concentrate, bend, or otherwise manage the light emitted street side according to various application parameters. In various embodiments, the inner and outer refractive surfaces 80 and 70 can be concave or convex. In one embodiment, the inner refractive surface 80 is convex and the outer refractive surface 70 is convex. In one embodiment, the inner refractive surface 80 is convex and the outer refractive surface 70 is concave. In one embodiment, the inner refractive surface 80 is concave and the outer refractive surface 70 is convex. In one embodiment, the inner refractive

7

surface **80** is concave and the outer refractive surface **70** is concave. In certain embodiments, at least one of the inner refractive surface **80** and the outer refractive surface **70** may be substantially planar or flat.

As shown in FIG. 2, the light emitting diode **10** further emits a section of light **210** that is headed house side or away from the street. This section of light **210** is incident upon an inner refractive surface **40** of the cavity **30** that forms a beam **200** within the optic **100**. The refractive surface **40** has an associated optical axis **45**. The optical axis **45** can form an angle with the optical axis **25** associated with the light emitting diode **10** itself. The optical axis **45** and the optical axis **25** can form an angle whether they actually intersect or not. The angle can be acute. In certain exemplary embodiments, the angle is between about 10 degrees and about 80 degrees, when measured in side view such as provided in FIG. 2. In certain exemplary embodiments, the angle is in a range between approximately 20 degrees and approximately 70 degrees. In certain exemplary embodiments, the angle is in a range between approximately 30 degrees and approximately 60 degrees. In certain exemplary embodiments, the angle is within 15 degrees of 45 degrees.

In the illustrated embodiment, the inner refractive surface **40** projects, protrudes, or bulges into the cavity **30**, which is typically filled with a gas such as air. In an exemplary embodiment, the refractive surface **40** can be characterized as convex and further as a collimating lens. The term “collimating,” as used herein in the context of a lens or other optic, generally refers to a property of causing light to become more parallel that the light would otherwise be in the absence of the collimating lens or optic. Accordingly, a collimating lens may provide a degree of focusing.

The beam **200** propagates or travels through the optic **100** along the optical axis **45** and is incident upon a reflective surface **50** that redirects the beam **200** towards an outer refractive surface **60**. The redirected beam **200** exits the optic **100** through the outer refractive surface **60**, which further steers the refracted beam **220** street side and can produce a desired level of beam spread. The reflective surface **50** is typically totally internally reflective as a result of the angle of light incidence exceeding the “critical angle” for total internal reflection. The reflective surface **50** is typically an interface between solid, transparent optical material of the optic **100** and a surrounding gaseous medium such as air.

Those of ordinary skill in the art having benefit of this disclosure will appreciate that the term “critical angle,” as used herein, generally refers to a parameter for an optical system describing the angle of light incidence above which total internal reflection occurs. The terms “critical angle” and “total internal reflection,” as used herein, are believed to conform with terminology commonly recognized in the optics field.

As illustrated in the FIG. 2, the refracted beam **220** (which is formed by the section of light **210** sequentially refracted, reflected, and refracted) and the twice refracted section of light (that is emitted by the street side of the light emitting diode) collectively provide street-side illumination.

In certain exemplary embodiments, the optic **100** is a unitary optical element that comprises molded plastic material that is transparent. In certain exemplary embodiments, the optic **100** is a seamless unitary optical element. In certain exemplary embodiments, the optic **100** is formed of multiple transparent optical elements bonded, fused, glued, or otherwise joined together to form a unitary optical element that is void of air gaps yet made of multiple elements.

FIG. 7 illustrates an exemplary array **800** of optics **100** provided in a sheet form to facilitate coupling multiple optics

8

100 to a corresponding array of light emitting diodes. Such an array of light emitting diodes would typically be under the illustrated sheet, and thus are not illustrated in FIG. 7. Accordingly, an illumination system can comprise a two-dimensional array of light sources, each comprising the illumination system **5** illustrated in exemplary form in FIG. 1 inter alia. The resulting two-dimensional array of light sources can comprise a light module or light bar, one or more of which can be disposed in a luminaire or other lighting apparatus, for example.

In certain exemplary embodiments, the array **800** can be formed of optical grade silicone and may be pliable and/or elastic, for example. In certain exemplary embodiments, the array **800** can be formed of an optical plastic such as polymethyl-methacrylate (“PMMA”), polycarbonate, or an appropriate acrylic, to mention a few representative material options without limitation.

Turning now to FIGS. 8, 9, and 10, these figures describe another exemplary embodiment of the present technology. FIG. 8 illustrates a perspective view of an optic **800** that manages light emitted from a light emitting diode **10**. The light emitting diode **10** is not illustrated in FIGS. 8, 9, and 10, but is depicted FIG. 1 and elsewhere as discussed above. Accordingly, the optic **800** can be coupled to a light emitting diode **10** or other light source for managing emitted light to form a light pattern comprising redirected light. FIG. 9 illustrates the optic **800** in side view overlaid with representative ray paths as would begin at a light emitting diode **10**.

FIG. 10 illustrates an exemplary diagram of photometric performance, wherein the lines plot common illuminance, analogous to how a contour map plots land elevation. Thus, FIG. 10 describes a computer-generated isofootcandle diagram of exemplary photometric performance for the optic of FIGS. 8 and 9 as coupled to a light emitting diode, with the lines depicting points of equal illuminance.

As shown in FIGS. 8 and 9, the optic **800** comprises an outer refractive surface **870**. Light emitted from the light emitting diode **10** in a street direction progresses towards the street through the outer refractive surface **870**, which can refract the light to produce desired beam spread. As discussed above, light emitted from a street-side of the light emitting diode **10** can propagate out of the light emitting diode, through an air gap, into the optic **800**, and then out of the optic **800** through the outer refractive surface **870**. Such an air gap may be filled with air, nitrogen, or other suitable gas.

Light emitted from the house side of the light emitting diode propagates through the cavity **830** and is incident upon an inner refractive surface **940** that forms a beam **920**. The beam **920** propagates through the optic and is incident upon a reflective surface **850** of the optic **800**. The reflective surface **850** directs the beam **920** out of the optic **800** through the outer refractive surface **860**, applying refraction to produce the beam **922** traveling towards the street as desired. In the illustrated embodiment, the outer refractive surface **860** is concave, but may be convex or substantially planar in other embodiments.

The reflective surface **850** can be oriented with respect to the beam **920** to exceed the “critical angle” for total internal reflection, so that the reflective surface **850** totally internally reflects the beam **920**. Accordingly, the internally reflective surface **850** can be formed by an interface between air and plastic or other transparent material of the optic **800**. Alternatively, the internally reflective surface **850** can comprise a reflective metallic coating.

FIGS. 11 and 12 describe certain exemplary embodiments in which an optic **1100** comprises multiple inner refractive surfaces **1150**, each forming a separate beam that is individu-

ally reflected and then refracted out of the optic **1100**. Similar to FIGS. **8**, **9**, and **10** as discussed above, a light generating element is not shown in FIG. **11** in order to promote reader visualization. In a typical application, the optic **1100** can be coupled to a light emitting diode **10** or other appropriate light source, and the optic **1100** can manage the generated light.

FIG. **12** illustrates the optic **1100** in side view overlaid with representative ray paths as would begin at an exemplary light emitting diode **10** (see light emitting diode **10** illustrated in FIG. **2**). In the illustrated embodiment, light emitted in the house side direction encounters the three inner refractive surfaces **1150**, each receiving a respective solid angle of emitted light. The three inner refractive surfaces **1150**, which can be convex from the illustrated viewing perspective, form three respective beams of light. As illustrated in FIG. **12** and discussed below, the three beams can have different focal lengths **1210**.

Three totally internally reflective features **1160** respectively reflect the three beams to increase street-side illumination. The configurations of the totally internally reflective features **1160** avoid occlusion or unwanted distortion of those three redirected beams thereby avoiding uncontrolled incidence or grazing off the outer surface of the optic **1100**. In the illustrated exemplary embodiment, two of the three totally internally reflective features **1160** are undercut, and all three jut outward.

FIG. **12** illustrates how the inner refractive surfaces **1150** create beams with different focal lengths **1210**, which would be reflected and refracted by the totally internally reflective features **1160** as shown in FIG. **11** in a physical implementation. That is, to convey an exemplary principle of the embodiment of FIG. **11**, FIG. **12** illustrates the three inner refractive surfaces **1150** forming three beams, and the beams are depicted as propagating within optical material of the optic **1100** without interacting with any subsequent optical features.

FIGS. **13A** and **13B**, **14**, **15**, **16**, and **17** describe certain exemplary embodiments in which the street side of the optic **1300** is smooth and the house side comprises prismatic grooves **1350**, as an exemplary embodiment of a pattern of retroreflectors. As illustrated, a reference plane **1368**, containing an optical axis **25**, that demarcates the two sides of the optic **1300** and can cut through the dome **20** of the light emitting diode **10** (see FIG. **1** as the dome is not labeled in FIG. **13B** to avoid line clutter). FIGS. **13A** and **13B** are renderings respectively illustrating the optic **1300** as an opaque solid and as a transparent line drawing that shows an exemplary light emitting diode **10** positioned to emit light into the optic **1300**.

In the illustrated illumination system **1390**, the prismatic grooves **1350** arch over the optic **1300** and the light emitting diode **10**. Light incident on the prismatic grooves **1350** is retroreflected back over the light emitting diode **10**, resulting in redirection to emerge from the smooth refractive surface **1325** headed in a street-side direction. In an exemplary embodiment, each prismatic groove **1350** comprises a retroreflector. Each prismatic groove **1350** comprises a pair of totally internally reflective surfaces **1375** or facets that collaboratively reflect light back in the general direction from which the light came. In certain exemplary embodiments, the totally internally reflective surfaces **1375** are substantially perpendicular to one another. In certain exemplary embodiments, the totally internally reflective surfaces **1375** meet to form a corner functioning as a retroreflecting edge of a cube, and may be characterized as a cube edge.

In operation, a light ray is incident on the first surface of the pair of totally internally reflective surfaces **1375**. The first

surface of the pair of totally internally reflective surfaces **1375** bounces the light to the second surface of the pair of totally internally reflective surfaces **1375**. The second surface of the pair of totally internally reflective surfaces **1375** bounces the light backwards, providing retroreflection. Accordingly, in certain exemplary embodiments, the pair of totally internally reflective surfaces **1375** can form a two-bounce retroreflector.

When viewed looking at the light emitting diode **10** straight down the optical axis **25**, as shown in FIG. **16**, the retroreflected light ray is parallel to the light ray incident on a prismatic groove **1350**. Meanwhile, if viewed in a side view taken for example perpendicular to the reference plane **1368**, the light ray would have an angle of reflection substantially equal to the angle of incidence. Accordingly, in the illustrated embodiment, the inclination of the light ray can be preserved (albeit reversed), so that the light ray can continue vertically, thereby retroreflecting back over the light emitting diode **10**.

FIG. **14** illustrates an intensity polar plot based on a computer simulation for the illumination system **1390**. FIG. **15** illustrates an isofootcandle plot based on a computer simulation for the illumination system **1390**. FIGS. **16** and **17** illustrate ray tracing analyses, from plan perspective, specifically looking down the optical axis **25**. FIGS. **16** and **17** further illustrate how varying the dimensions of the prismatic grooves **1350/1775** can control the level of light leaking through the prismatic grooves as a result of certain rays being oriented for total internal reflection while other rays are oriented below the critical angle and will be refracted out of the prismatic groove. Increasing groove width, as illustrated in FIG. **17**, can increase house-side illumination, for example.

An exemplary process for managing light emitted by a light emitting diode **10** will now be discussed in further detail with reference to FIG. **18**, which illustrates a flow chart of an embodiment of such a process in the form of process **1800**, entitled "Manage Light."

Certain steps in the processes described herein may naturally precede others for the present technology to function as taught. However, the present technology is not limited to the order of the steps described if such order or sequence does not alter the functionality of the present technology to the level of rendering the technology inoperative or nonsensical. That is, it is recognized that some steps may be performed before or after other steps or in parallel with other steps without departing from the scope and spirit of the present technology.

The following discussion of process **1800** will refer to certain elements illustrated in FIGS. **1**, **2**, **3**, **4**, **5A**, **5B**, **5C**, **5D**, **5E**, **6A**, **6B**, **6C**, **6D**, and **6E**. However, those of skill in the art will appreciate that various embodiments of process **1800** can function with and/or accommodate a wide range of devices, systems, and hardware (including elements illustrated in other figures as well as elements not expressly illustrated) and can function in a wide range of applications and situations. Accordingly, such referenced elements are exemplary, are provided without being exhaustive and without limitation, and are among many other supported by the present technology.

Referring now to FIG. **18**, at step **1805** of process **1800**, the light emitting diode **10** converts electricity into light and emits light. The emitted light and/or the light emitting diode **10** has an associated optical axis **25**. A portion of the emitted light is emitted in the street-side direction. Another portion, including the section **210**, is emitted in the house-side direction.

At step **1810**, the inner refractive surface **80** and the outer refractive surface **70** of the optic **100** transmit and refract the light emitted in the desired, street-side direction. Accordingly, the optic **100** directs light to and illuminates the street.

11

At step **1815**, which typically proceeds substantially in parallel with step **1810**, the section of light **210** that is headed house side encounters the inner refractive surface **40** of the optic **100**. The inner refractive surface **40** forms a beam **200** propagating within the solid optical material of the optic **100**, along the optical axis **45**. The optical axis **45** is typically oriented at an acute angle relative to the optical axis **25** and/or with respect to the light emitting diode's substrate (e.g. the flat portion of the LED chip from which the dome **20** projects).

At step **1820**, which likewise typically proceeds substantially in parallel with step **1810**, the beam **200** encounters the reflective surface **50**, which is typically totally internally reflective but may be mirrored with a metal coating as an alternative suitable for certain applications. The reflective surface **50** reverses the beam **200**, sending the beam **200** in a street-side direction.

At step **1825**, the beam **200** exits the optic **100** heading street side, and may be refracted upon exit. Step **1825** may likewise proceed substantially in parallel with Step **1810**.

At step **1830**, the optic **100** emits a pattern of light that, as illustrated in FIG. **10**, can be biased towards a street. Process **1800** iterates from step **1830**, and management of light to provide biased illumination continues.

Technology for managing light emitted from a light emitting diode or other source has been described. From the description, it will be appreciated that an embodiment of the present technology overcomes the limitations of the prior art. Those skilled in the art will appreciate that the present technology is not limited to any specifically discussed application or implementation and that the embodiments described herein are illustrative and not restrictive. From the description of the exemplary embodiments, equivalents of the elements shown therein will suggest themselves to those skilled in the art, and ways of constructing other embodiments of the present technology will appear to practitioners of the art. Therefore, the scope of the present technology is to be limited only by the claims that follow.

What is claimed is:

1. An illumination system comprising:

an optic comprising a first surface that defines a cavity and a second surface opposite the first surface; and

a light emitting diode disposed at least partially in the cavity, the light emitting diode having a first optical axis,

wherein a cross section of the optic taken at the optical axis of the light emitting diode shows asymmetry of the first surface with respect to the optical axis and asymmetry of the second surface with respect to the optical axis, and the cross section includes:

the second surface having a first and second portion both substantially located on a first side of the optical axis, wherein the first portion is a total internally reflective (TIR) surface and the second portion is a refractive surface, and

wherein the first surface of the optic includes a convex focusing element that is substantially located on the first side of the optical axis, wherein a portion of light emitted by the light emitting diode on the first side of the optical axis is focused by the focusing element outward with respect to the optical axis and toward the TIR surface, wherein the TIR surface reflects the focused light toward the refractive surface that refracts the reflected light across the optical axis to a second side of the optical axis, so that the illumination system produces an overall illumination pattern that is biased to the second side of the axis.

12

2. The illumination system of claim **1**, wherein the convex focusing element is configured to project a substantially collimated beam of light onto the TIR surface.

3. The illumination system of claim **2**, wherein the TIR surface comprises an air interface.

4. The illumination system of claim **1**, wherein the TIR surface is located entirely on the first side of the optical axis.

5. The illumination system of claim **1**, wherein the illumination system is a street luminaire.

6. The illumination system of claim **1**, wherein the optic is seamless, and wherein a light emitting dome of the light emitting diode protrudes into the cavity.

7. The illumination system of claim **1**, wherein a gas is disposed between the light emitting diode and the first surface.

8. The illumination system of claim **1**, wherein the optic is one optic in an array of optics.

9. The illumination system of claim **1**, wherein the optic comprises a street side and a house side, wherein the house side of the optic is disposed on the first side of the optical axis, and wherein the street side of the optic is disposed on the second side of the optical axis.

10. The illumination system of claim **1**, wherein the refractive surface is concave and is located entirely on the first side of the optical axis.

11. An apparatus comprising:

a light emitting diode (LED) having an optical axis; and a lens, wherein the lens includes an inner surface and an outer surface, wherein the inner surface faces the LED, and wherein a cross section of the lens taken at the optical axis of the LED shows asymmetry of the inner surface with respect to the optical axis and asymmetry of the outer surface with respect to the optical axis, and the cross section of the lens includes:

the outer surface having a first and second portion both substantially located on a first side of the optical axis, wherein the first portion is a total internally reflective (TIR) surface and the second portion is a refractive surface, and

wherein the inner surface of the lens includes a convex focusing element that is substantially located on the first side of the optical axis, wherein a portion of light emitted by the LED on the first side of the optical axis is focused by the focusing element toward the TIR surface with the focused light and the optical axis forming an acute angle, wherein the TIR surface reflects the focused light toward the refractive surface that refracts the reflected light across the optical axis to a second side of the optical axis, so that the apparatus outputs an overall illumination pattern that is biased to the second side of the axis.

12. The apparatus claim **11**, wherein the convex focusing element is configured to project a substantially collimated beam of light onto the TIR surface.

13. The apparatus of claim **12**, wherein the TIR surface comprises an air interface.

14. The apparatus of claim **11**, further comprising an array of lenses, wherein the array of lenses includes the lens.

15. The apparatus of claim **11**, wherein a sheet of lenses comprises said lens and is configured for coupling to an array of LEDs that comprises said LED.

16. The apparatus of claim **11**, wherein the lens comprises a street side and a house side, the house side of the lens disposed on the first side of the optical axis, the street side of the lens disposed on the second side of the optical axis.

13

17. The apparatus of claim 11, comprising a street luminaire.

18. A lens comprising:

an inner surface and an outer surface, wherein the inner surface faces a light emitting diode (LED), and wherein a cross section of the lens taken at an optical axis of the LED shows asymmetry of the inner surface with respect to the optical axis and asymmetry of the outer surface with respect to the optical axis, and the cross section of the lens includes:

the outer surface having a first and second portion both substantially located on a first side of the optical axis, wherein the first portion is a total internally reflective (TIR) surface and the second portion is a refractive surface, and

wherein the inner surface of the lens includes a convex focusing element that is substantially located on the

14

first side of the optical axis, wherein a portion of light emitted by the LED on the first side of the optical axis is focused by the focusing element toward the TIR surface with the focused light and the optical axis forming an acute angle, wherein the TIR surface reflects the focused light toward the refractive surface that refracts the reflected light across the optical axis to a second side of the optical axis, resulting in an overall illumination pattern that is biased to the second side of the axis.

19. The lens of claim 18, wherein the lens is one lens in an array of lenses.

20. The apparatus of claim 18, wherein the lens comprises a street side and a house side, the house side of the lens disposed on the first side of the optical axis, the street side of the lens disposed on the second side of the optical axis.
